Subclassification of steatotic liver disease

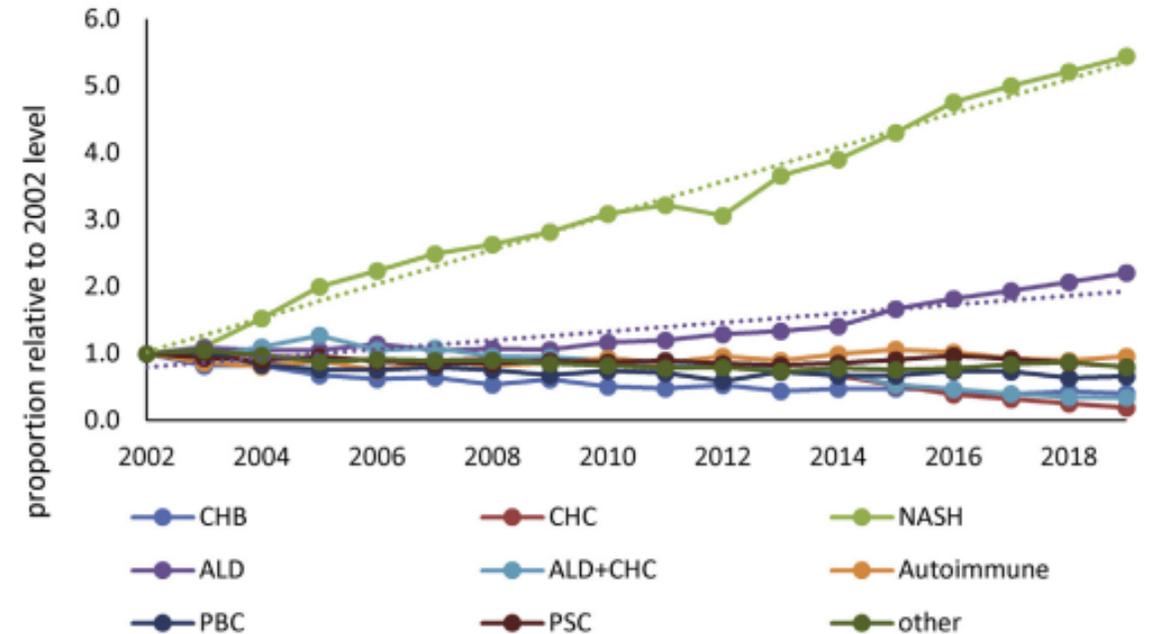

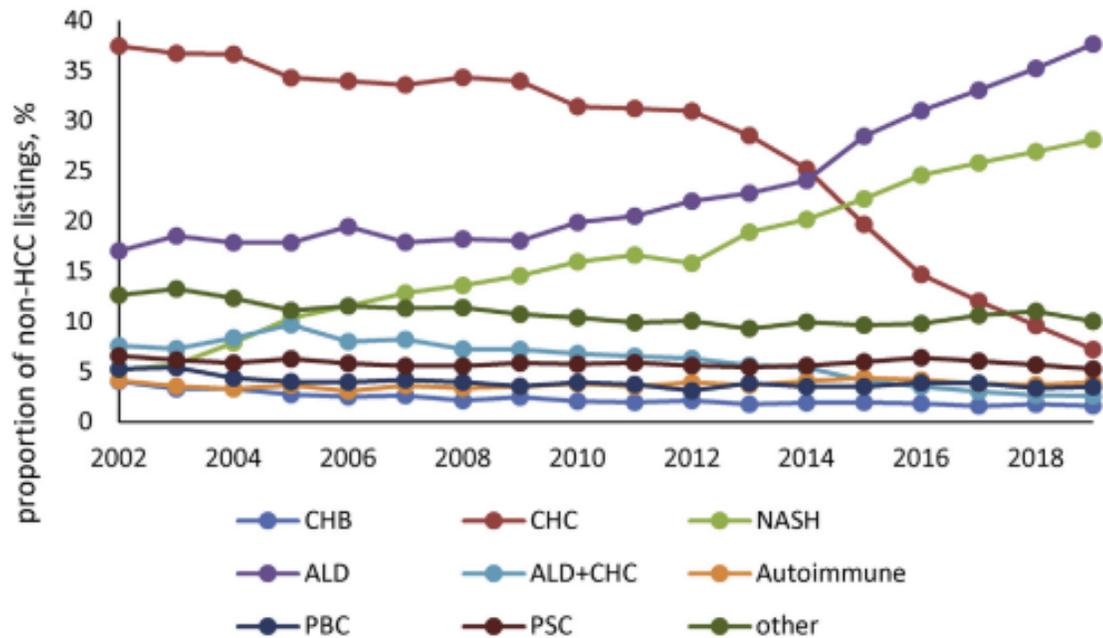

Global prevalence of MASLD in 1990-2019

Pooled Prevalence of NAFLD: 30.05% (95% confidence interval: 27.88 to 32.32%)

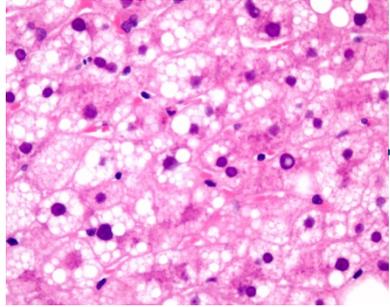

MASH is a rapidly increasing indication for liver transplantation in USA

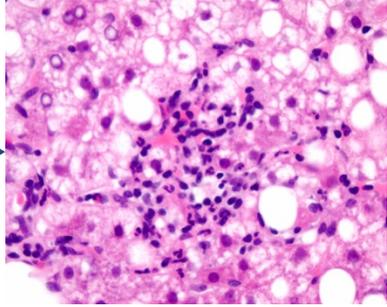

Scientific Registry of Transplant Recipients (2002-2019): N=168,441

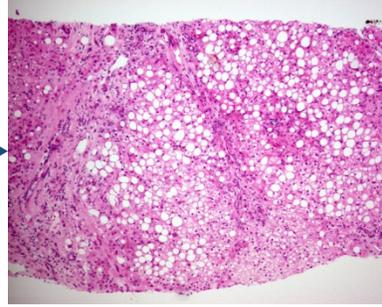

Natural history of MASLD

Metabolic dysfunction-associated steatotic liver (MASL) = simple steatosis

Metabolic dysfunction-associated steatohepatitis (MASH)

Progressive liver fibrosis

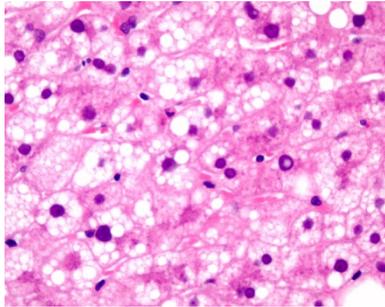

Cirrhosis

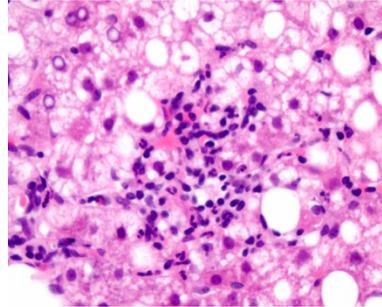

Decompensation, HCC and death

Why assess steatosis, inflammation, and fibrosis?

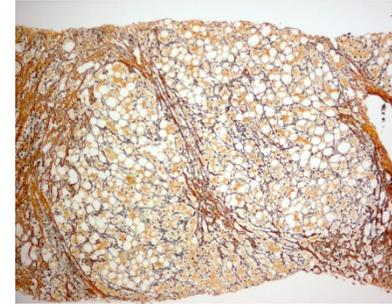

Steatosis

- Basis to diagnose SLD
- Reflects treatment response

Inflammation

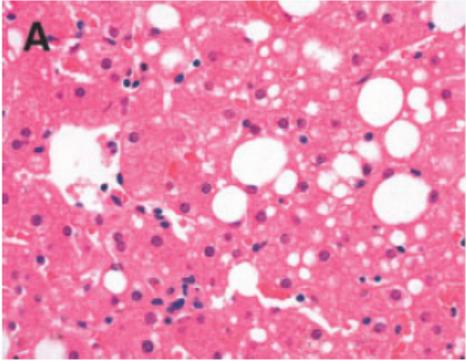

- More active progression
- Target population for trial enrolment
- Reflects treatment response

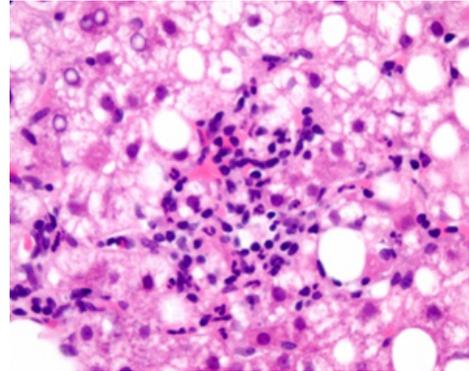

Fibrosis

- Most prognostic
- Target population for trial enrolment
- Reflects treatment response

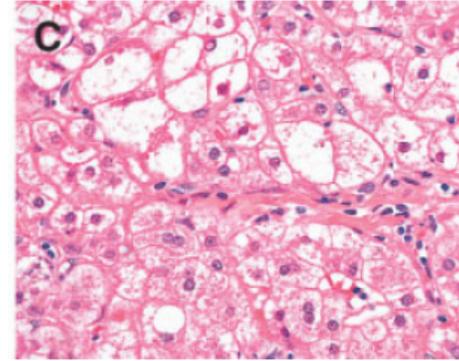

Liver biopsy for MASLD

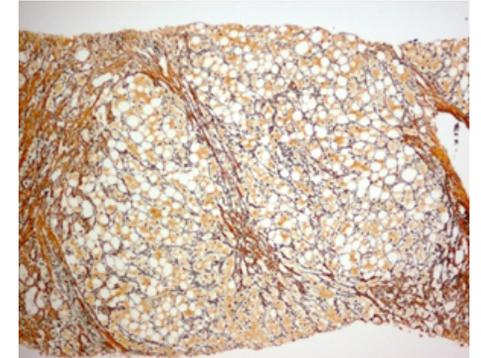

Steatosis

Lobular
inflammation

Hepatocyte
ballooning

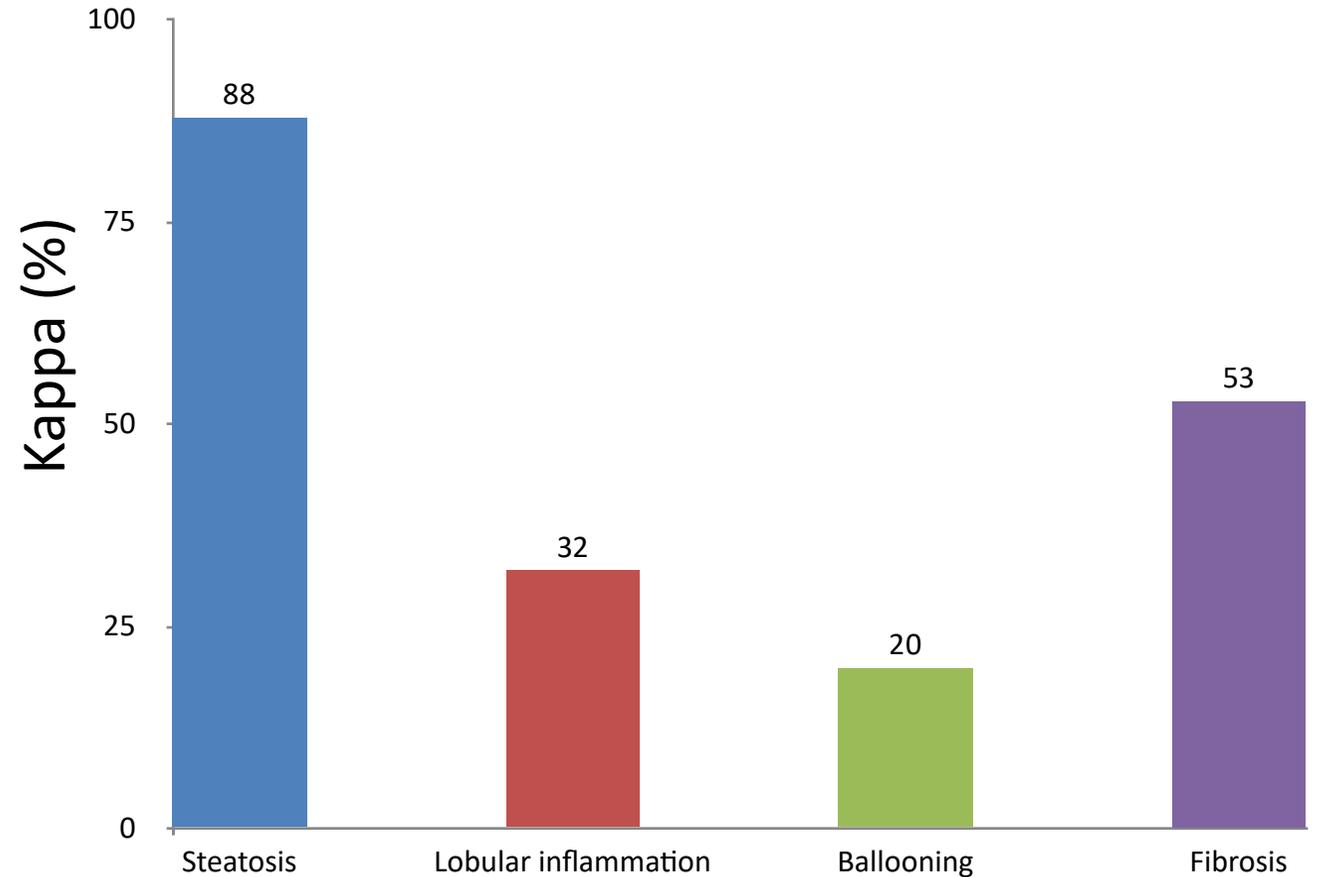

Fibrosis

$$\text{NAFLD activity score (0-8)} = \text{Steatosis (0-3)} + \text{Lobular inflammation (0-3)} + \text{Hepatocyte ballooning (0-2)}$$

Problems with liver biopsy

- Contraindications
 - Bleeding tendency
 - Ascites
- Complications
 - Pain
 - Bleeding
- Sampling error

N=41, biopsies of both lobes of liver

Merriman et al. Hepatology 2006;44:874

While it is desirable to have a single biomarker fulfilling all of the above (e.g., HbA_{1c} for diabetes), it is not a must.

Clinical outcomes

PHT, portal hypertension

MALO, major adverse liver outcomes

Diagnosis of MASLD

- Hepatic steatosis by imaging, blood biomarkers/scores or histology
- USG: Bright liver echotexture, deep attenuation, vascular blunting
- Presence of ≥ 1 of 5 cardiometabolic risk factors

Prediction models of hepatic steatosis

Fatty Liver Index

Diagnoses fatty liver using labs and exam findings.

<input type="button" value="» Next Steps"/>	<input type="button" value="📄 Evidence"/>	<input type="button" value="👤 Creator Insights"/>

Advantages

- Inexpensive
- Possible to study epidemiology of SLD in large retrospective registries when imaging is not available

Disadvantages

- Less helpful for individual patients
- Confounded by metabolic factors (e.g., cannot determine if adverse outcomes are due to SLD or obesity)
- Confounded by treatment

Vibration-controlled transient elastography (FibroScan)

Controlled attenuation parameter (CAP)

- Measures ultrasound attenuation
- Reflects hepatic steatosis

Liver stiffness measurement (LSM)

- Measures shear wave velocity
- Reflects liver fibrosis

Diagnostic performance of CAP for hepatic steatosis

M probe

	S0 vs. S1-S3	S0-S1 vs. S2-S3	S0-S2 vs. S3
AUC	0.82	0.87	0.88
Sensitivity	69%	77%	88%
Specificity	82%	81%	78%
Optimal cutoff, dB/m	248	268	280

XL probe

Specificity	74%	63%	60%
Optimal cutoff, dB/m	297	317	333

Continuous CAP to reduce variability

>200 measurements are taken
with continuous CAP

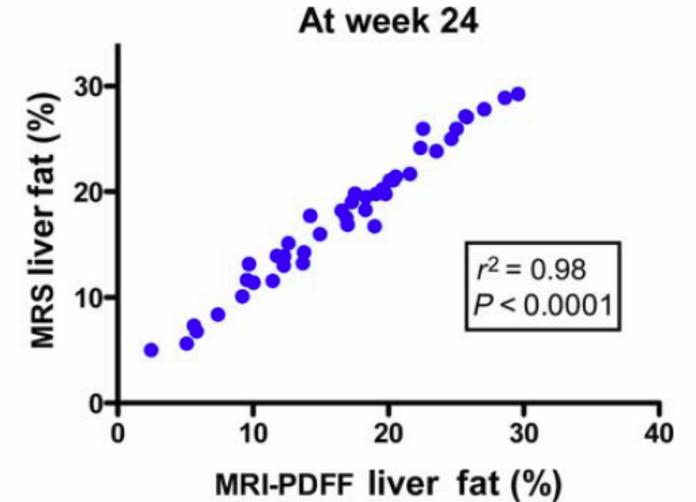

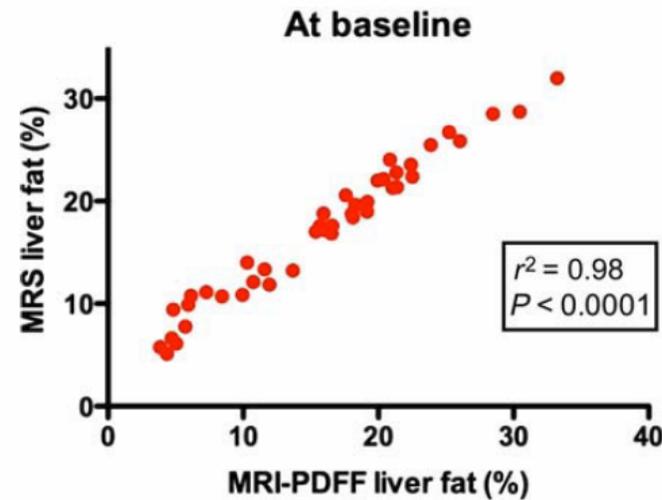

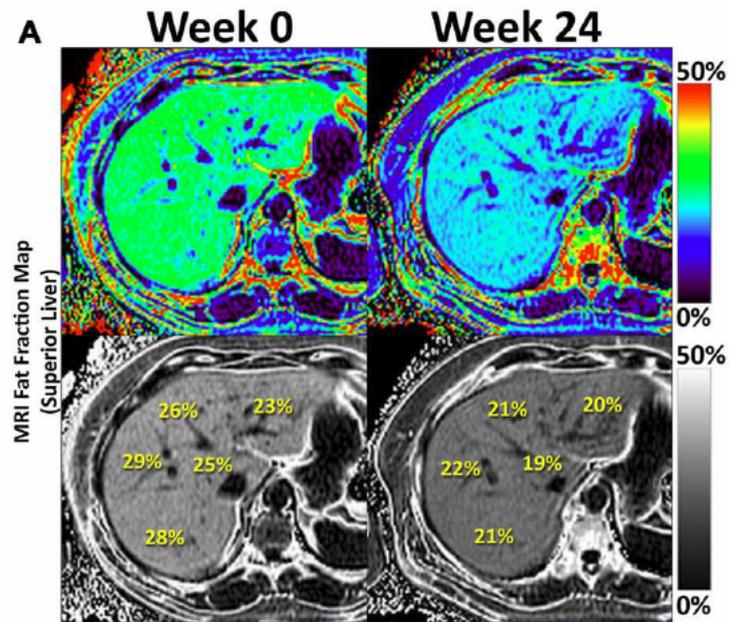

MASLD-CAP-MON Study design overview (N=150)

Visit	Screening	Baseline	Month 3	Month 6
Questionnaires		X	X	X
BW, BH, WC, HC, BP	X	X	X	X
Blood tests	X		X	X
HBsAg, anti-HCV	X			
VCTE	X		X	X
USG	X			X
MRI-PDFF	X			X

MRI assessment of hepatic steatosis

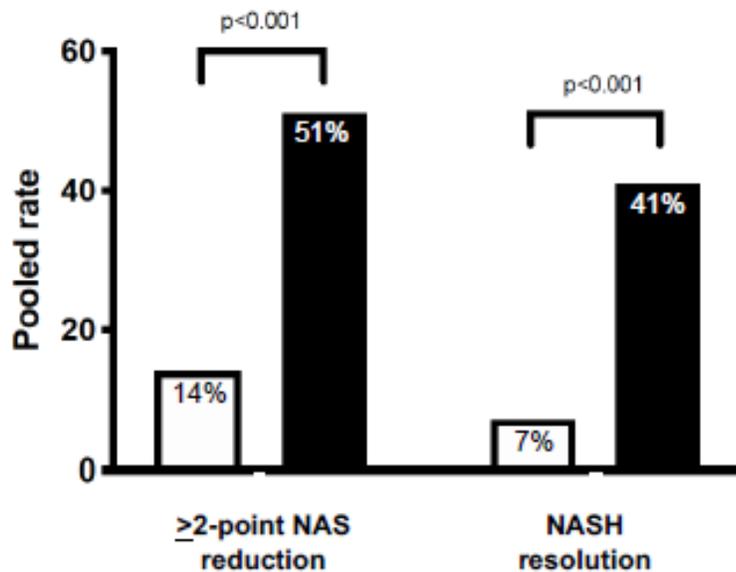

- Highly reproducible
- Not affected by obesity
- Expensive and limited availability

PDFF: proton density fat fraction

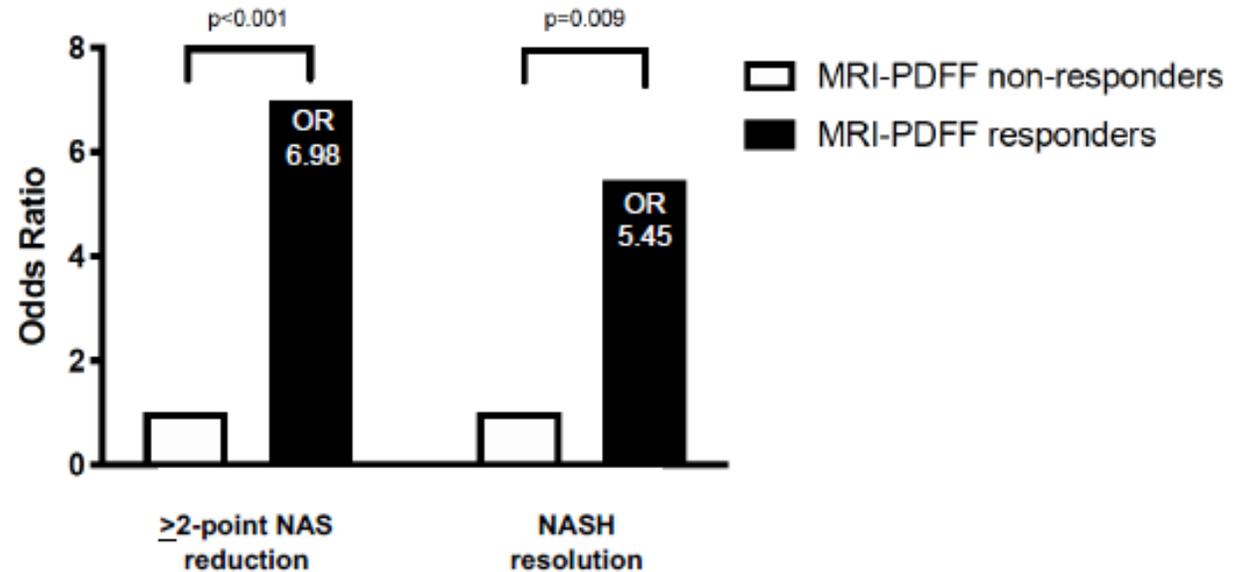

MRS: magnetic resonance spectroscopy

Histologic response in patients with $\geq 30\%$ relative reduction in MRI-PDFF

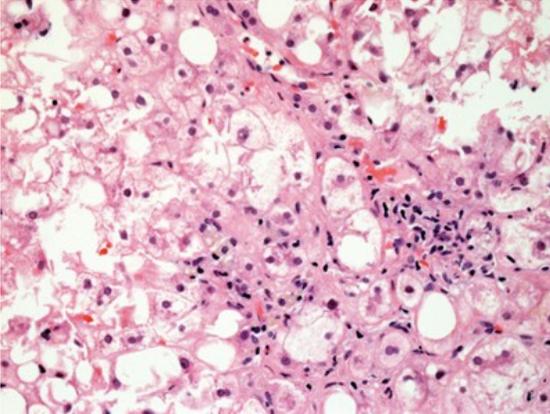

A. Rate of histologic response between MRI-PDFF responders versus non-responders

B. Odds of histologic response between MRI-PDFF responders versus non-responders

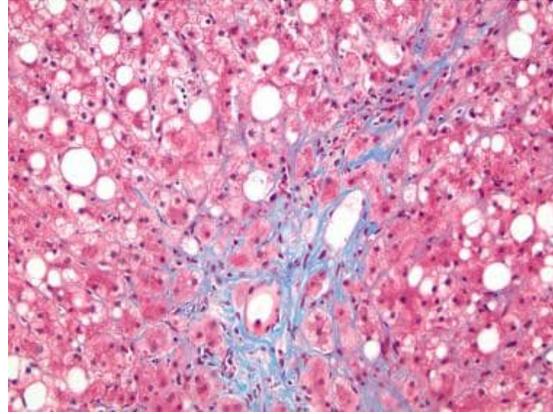

Key diagnostic targets for MASLD

Metabolic dysfunction-associated steatohepatitis (MASH)

Characterized by steatosis, lobular inflammation and hepatocyte ballooning

Liver fibrosis and cirrhosis
Strongly associated with liver-related outcomes

At-risk MASH

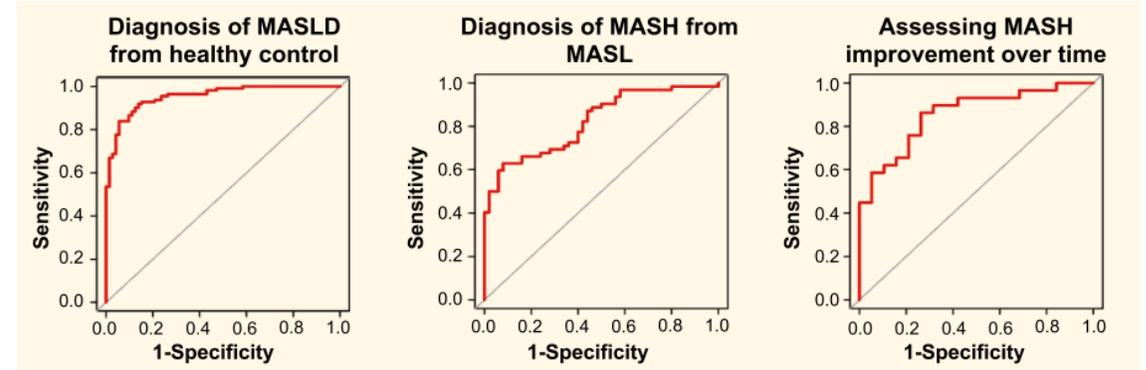

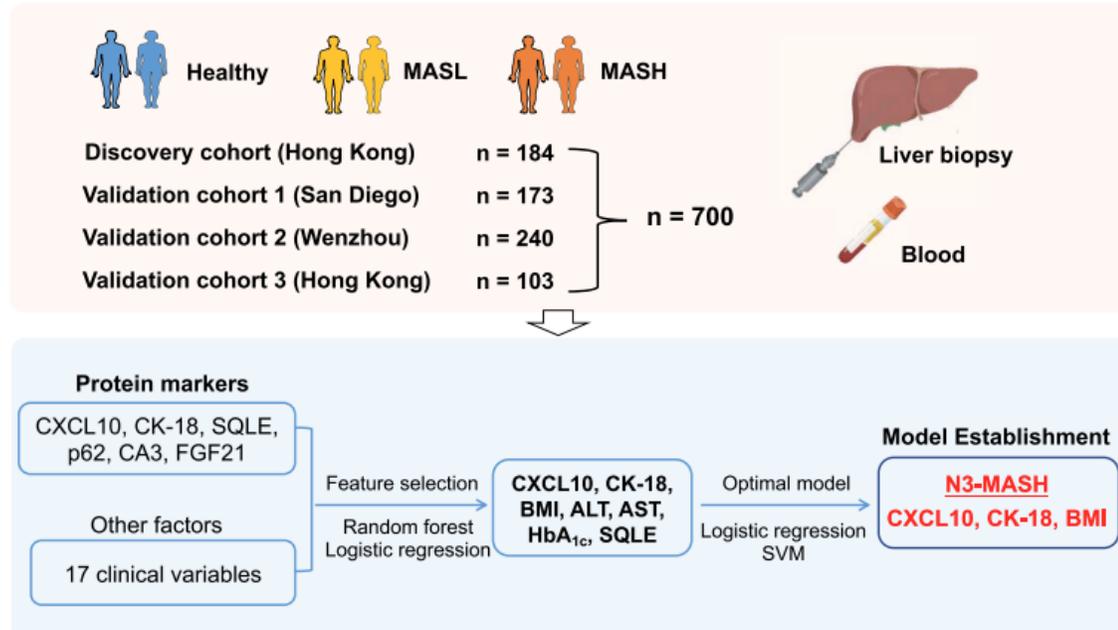

=

1. MASLD activity score ≥ 4
2. ≥ 1 point each in steatosis, lobular inflammation and ballooning
3. F2-F3 fibrosis

Performance of NITs of at-risk MASH

Target: At-risk MASH = (1) NAFLD activity score ≥ 4 , (2) steatosis, lobular inflammation and hepatocyte ballooning each \geq grade 1, and (3) F2-F3 fibrosis

AUROC 0.95

0.82

0.86

But are MASH biomarkers required?

AASLD Guidance on Resmetirom Therapy

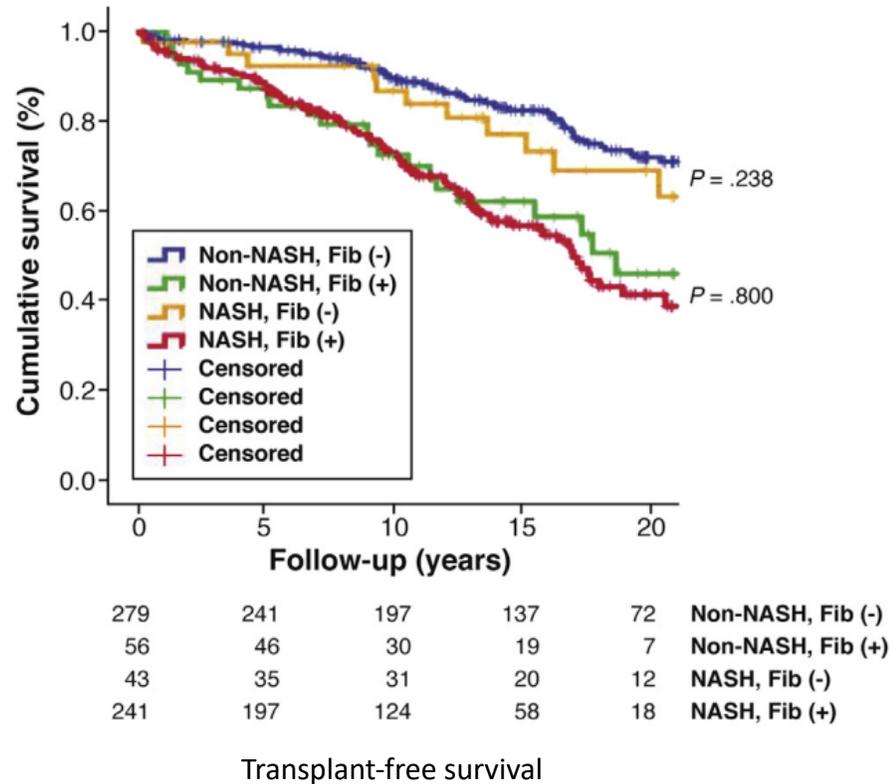

^a Modified from the AASLD NILDA guidelines.⁵

^b Liver biopsy is not routinely recommended for staging of MASH.

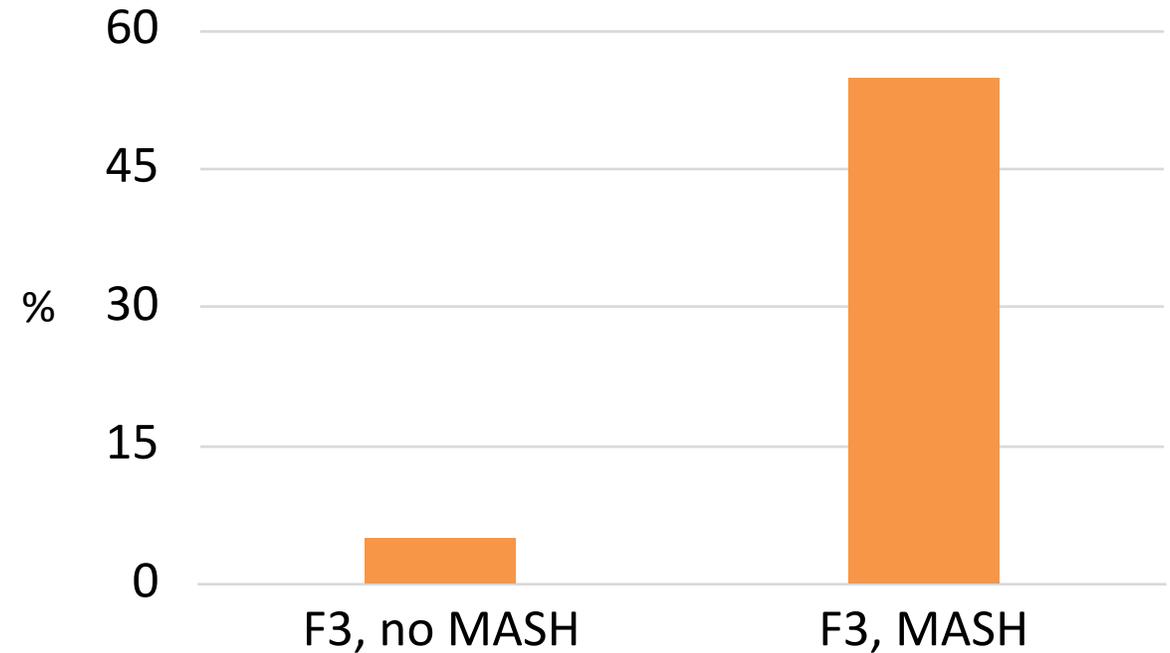

^c Imaging-based NILDA is preferred, eg, shear wave elastography (applying local standards for F2-F3) versus enhanced liver fibrosis score (9.2-10.4). The latter range is based on the interquartile range from the MAESTRO trial data; no recommendations are available from the AASLD NILDA guidelines.⁶

Potential role of MASH biomarkers

Fibrosis trumps MASH in prognostication

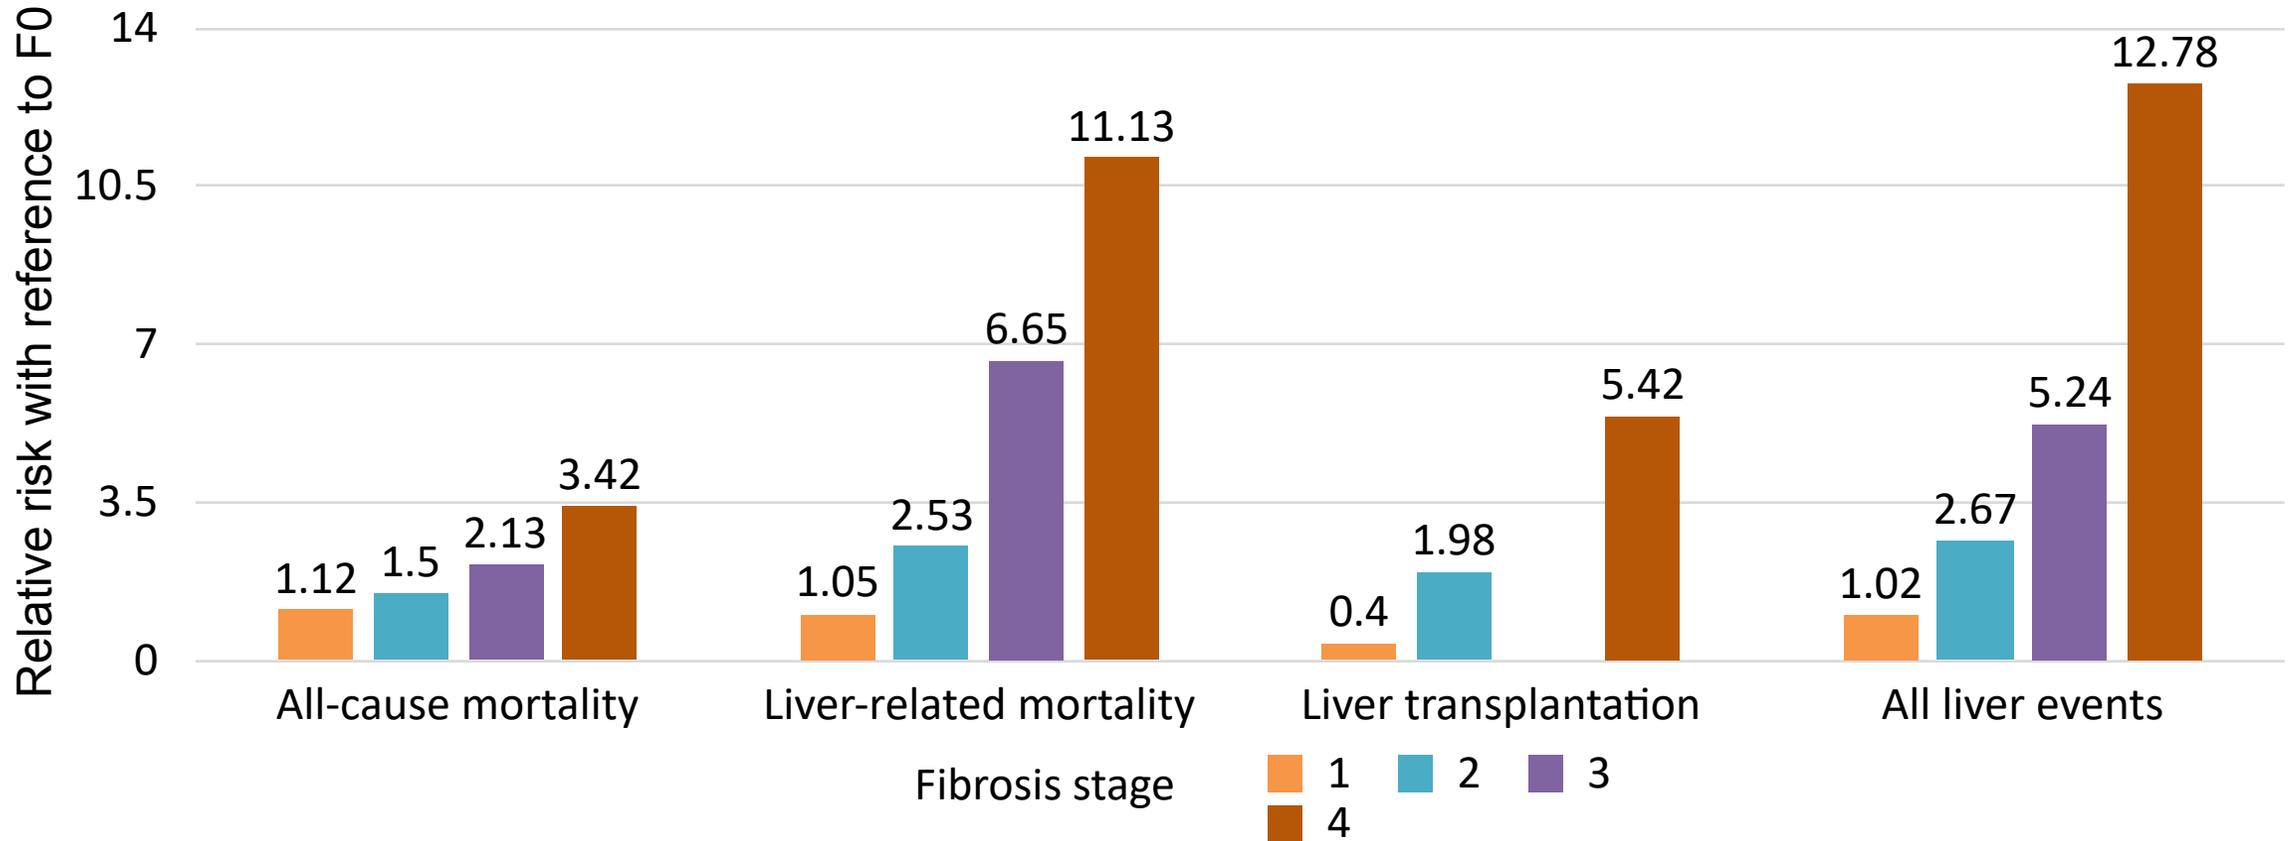

The only use of MASH biomarkers is if they can predict response to treatment

However, as most drug trials only include patients with MASH, whether a drug works differently in patients with low disease activity is currently unknown

Fibrosis stage and clinical outcomes of MASLD

Fibrosis-4 (FIB-4) Index for Liver Fibrosis

Noninvasive estimate of liver scarring in HCV and HBV patients, to assess need for biopsy.

VCTE-Prognosis Study Group

- 17,949 patients with MASLD who underwent VCTE from 16 centers (prospective at 14 centers)
- 14,845 Asian countries/regions
 - 9,556 Korea
 - 4,037 Hong Kong
 - 474 Japan
 - 366 China
 - 211 Singapore
 - 201 Malaysia
- 3,104 Western countries
 - 1,183 Italy
 - 724 United Kingdom
 - 382 France
 - 352 Spain
 - 302 Sweden
 - 161 United States

Study design

- We included adult patients with MASLD who underwent at least 1 additional VCTE exam within 6-60 months after the first VCTE
- We excluded patients with LREs before the first VCTE, or between the VCTE examinations in 6-60 months

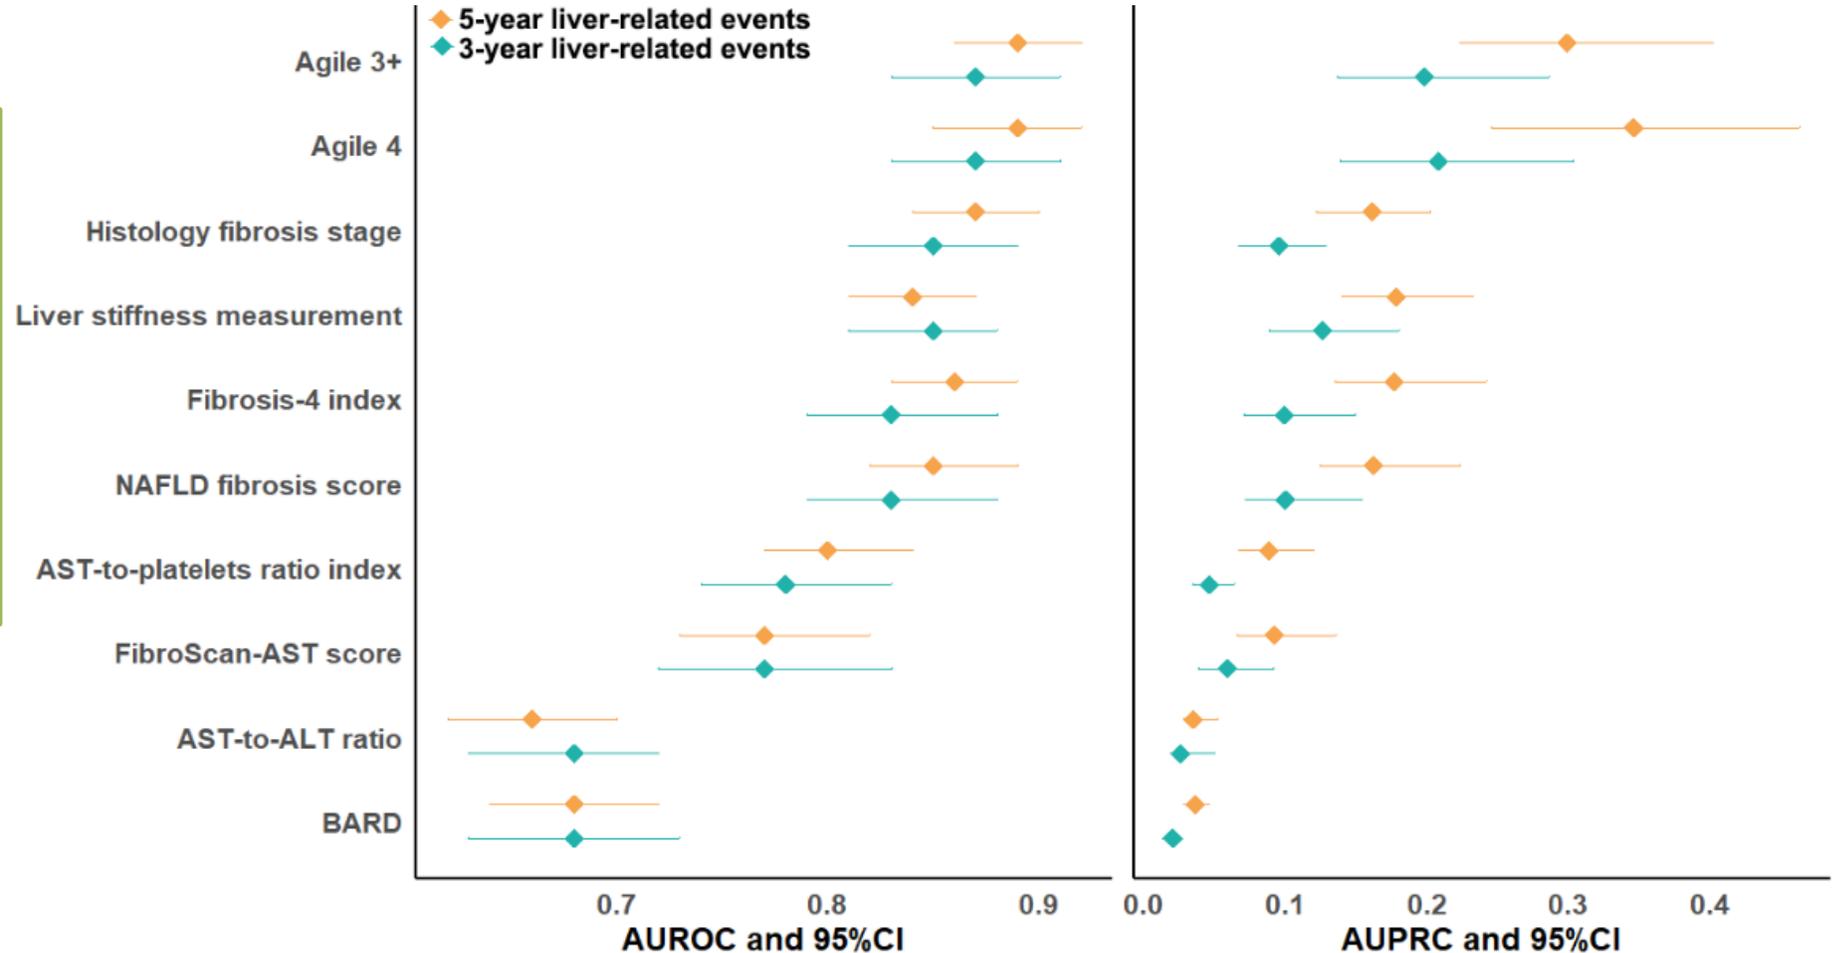

Liver-related events (LREs) = hepatic decompensation (ascites, variceal hemorrhage, hepatic encephalopathy, hepatorenal syndrome-acute kidney injury), HCC, liver transplantation, or liver-related death

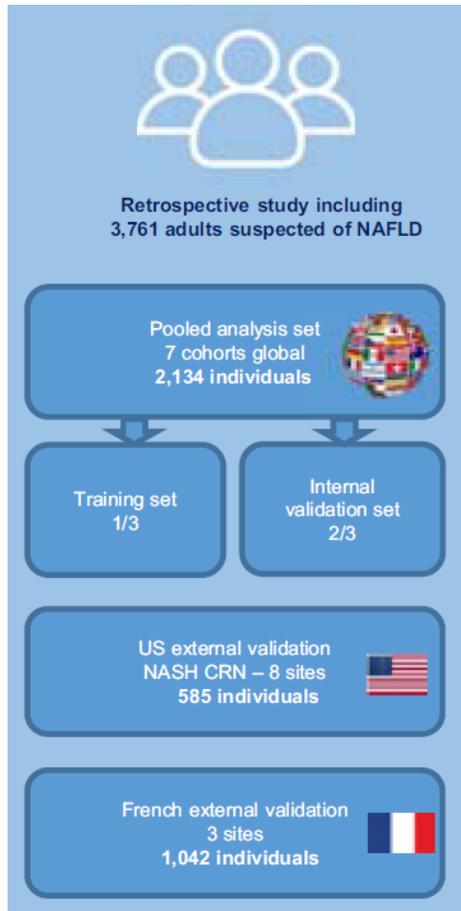

Agile scores are superior to histologic fibrosis stage and other fibrosis scores in prognostication

16 603 patients with MASLD from 16 centers in the US, Europe and Asia (prospective data from 14 centers)

316 liver-related events (LREs; 139 HCC and 209 hepatic decompensation) at a median FU of 52 months

Agile scores for F3 and F4 fibrosis

Magnetic resonance elastography and liver-related events

Six international cohorts with nonalcoholic fatty liver disease

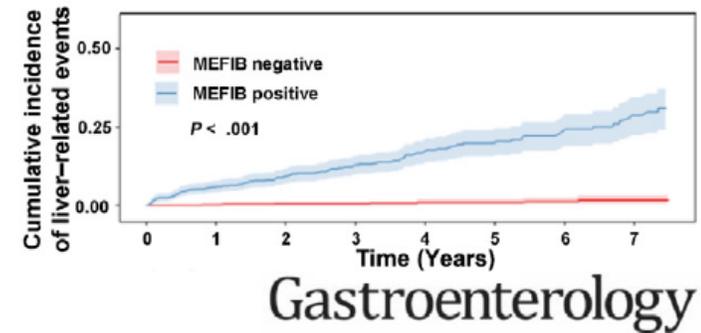

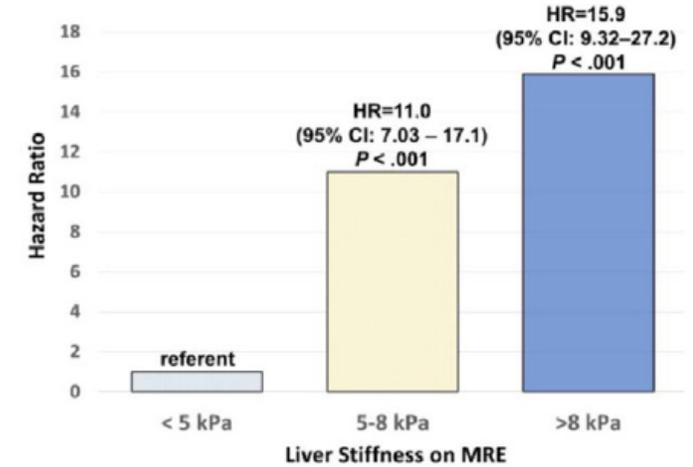

Underwent magnetic resonance elastography

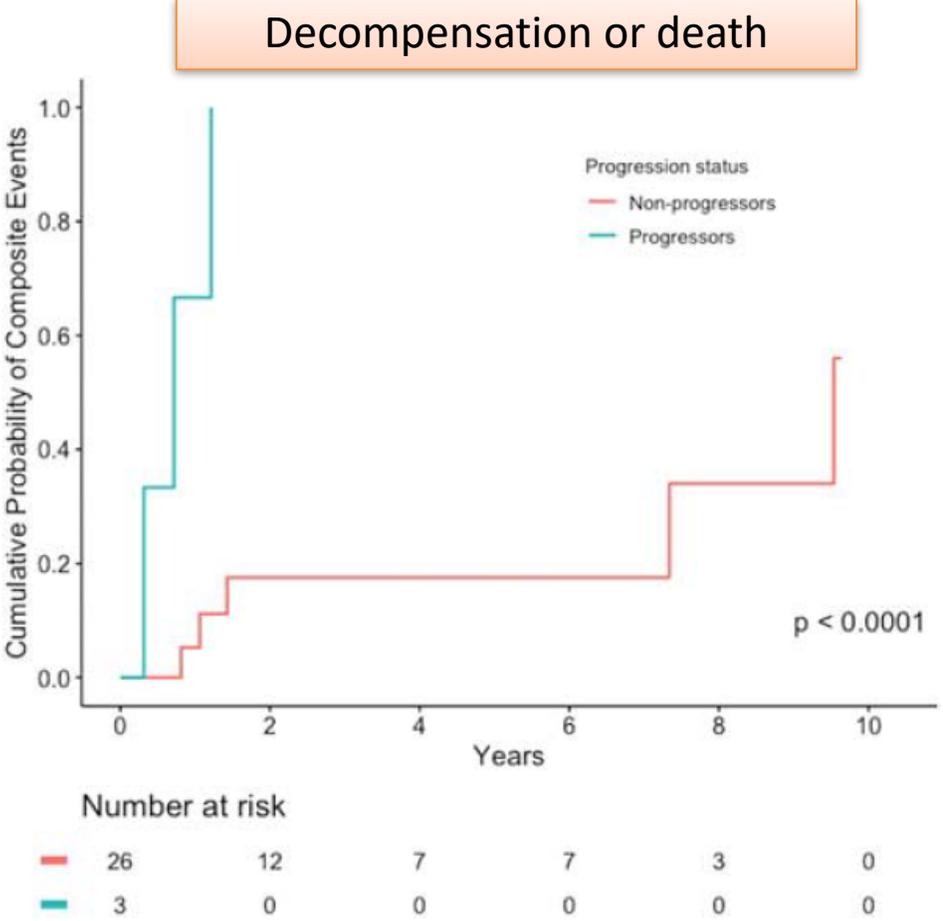

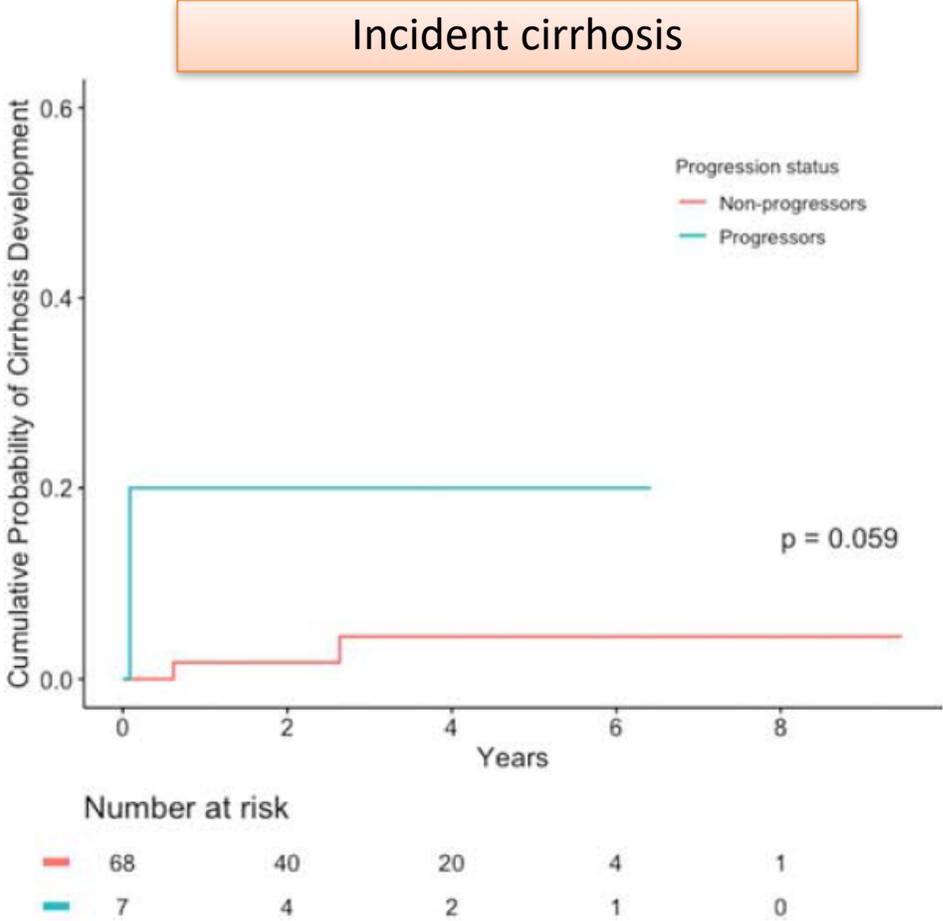

Liver stiffness assessed by MRE is associated with development of ascites, hepatic encephalopathy and varices needing treatment

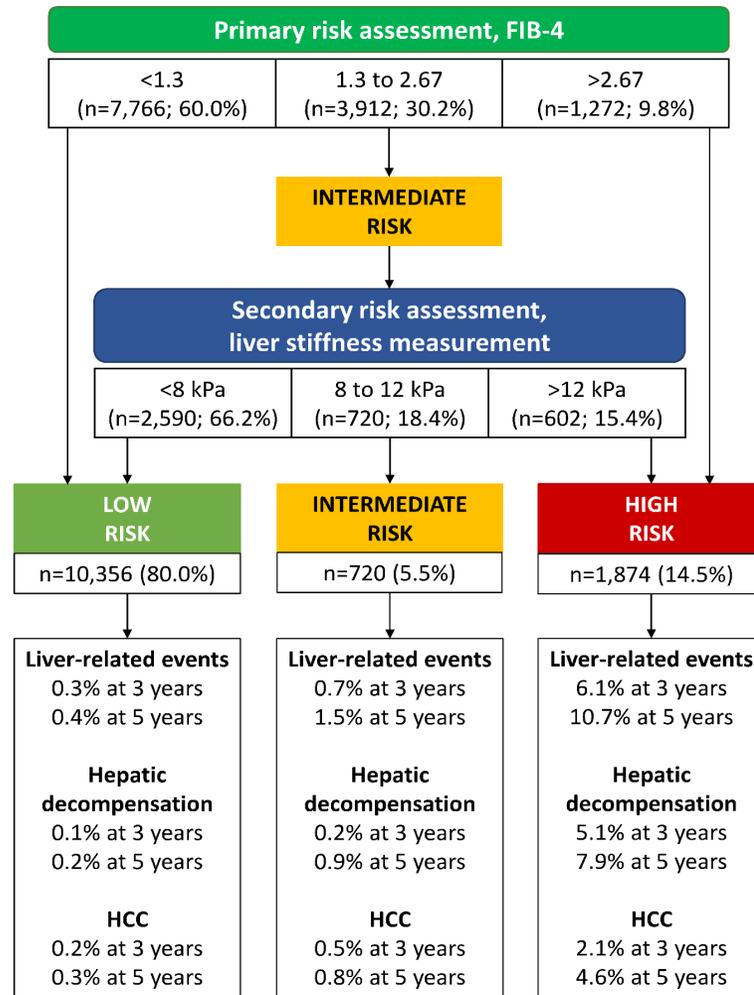

The MEFIB combination of MRE and FIB-4 (defined as positive when MRE ≥ 3.3 kPa and FIB-4 ≥ 1.6) has excellent negative predictive value for hepatic decompensation.

Serial MRE and liver-related events in MASLD

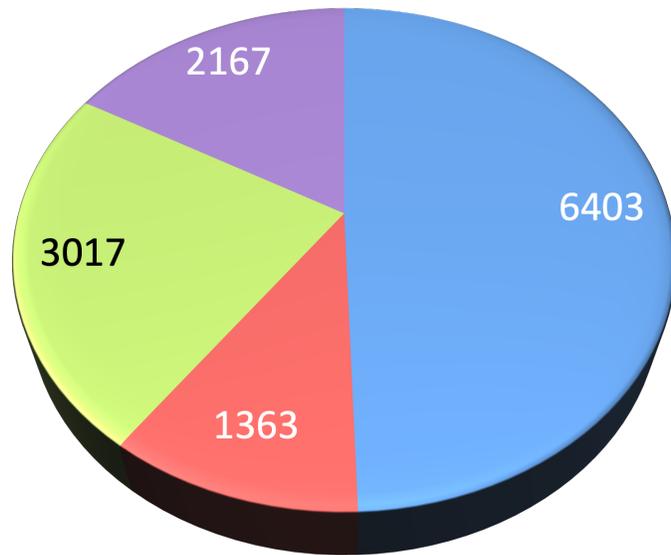

Prognostication by the 2-step approach

Key findings:

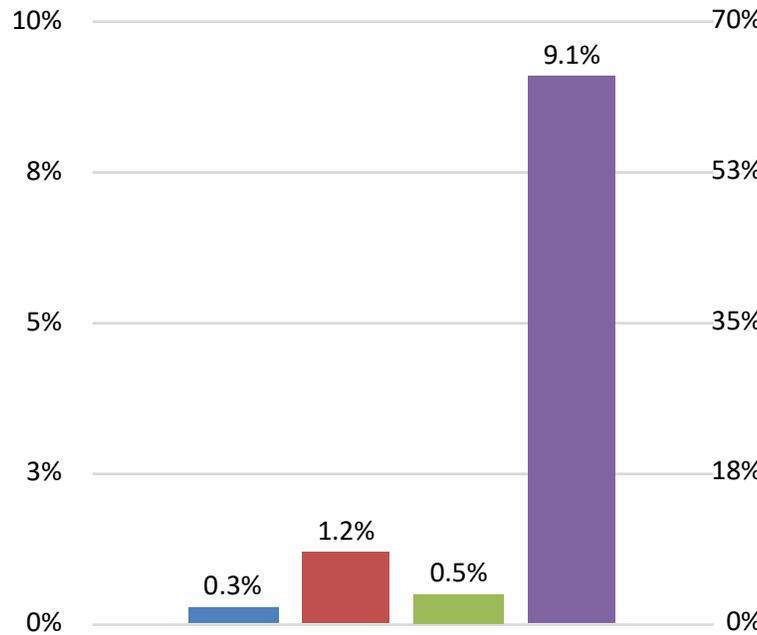

1. The 2-step approach is prognostic
2. With FIB-4 as the first-line test, the use of the Agile scores as the second-line test is not better than VCTE-LSM alone
3. Reserving VCTE-LSM for patients with FIB-4 1.3-2.67 is as good as VCTE-LSM for all patients

How to interpret discrepant results between FIB-4 and VCTE-LSM?

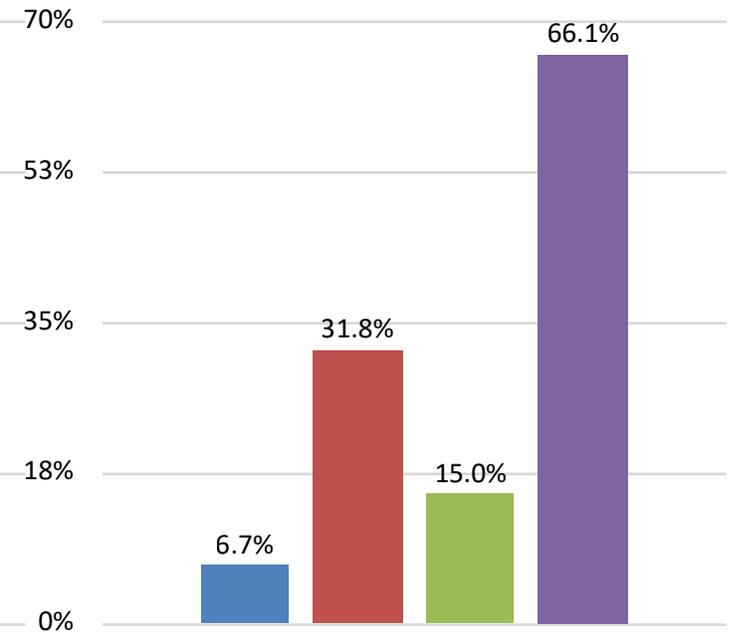

- FIB-4 <1.3, LSM <8
- FIB-4 <1.3, LSM ≥8
- FIB-4 ≥1.3, LSM <8
- FIB-4 ≥1.3, LSM ≥8

Liver-related events

- FIB-4 low, LSM low
- FIB-4 low, LSM high
- FIB-4 high, LSM low
- FIB-4 high, LSM high

Histological F3-F4 fibrosis

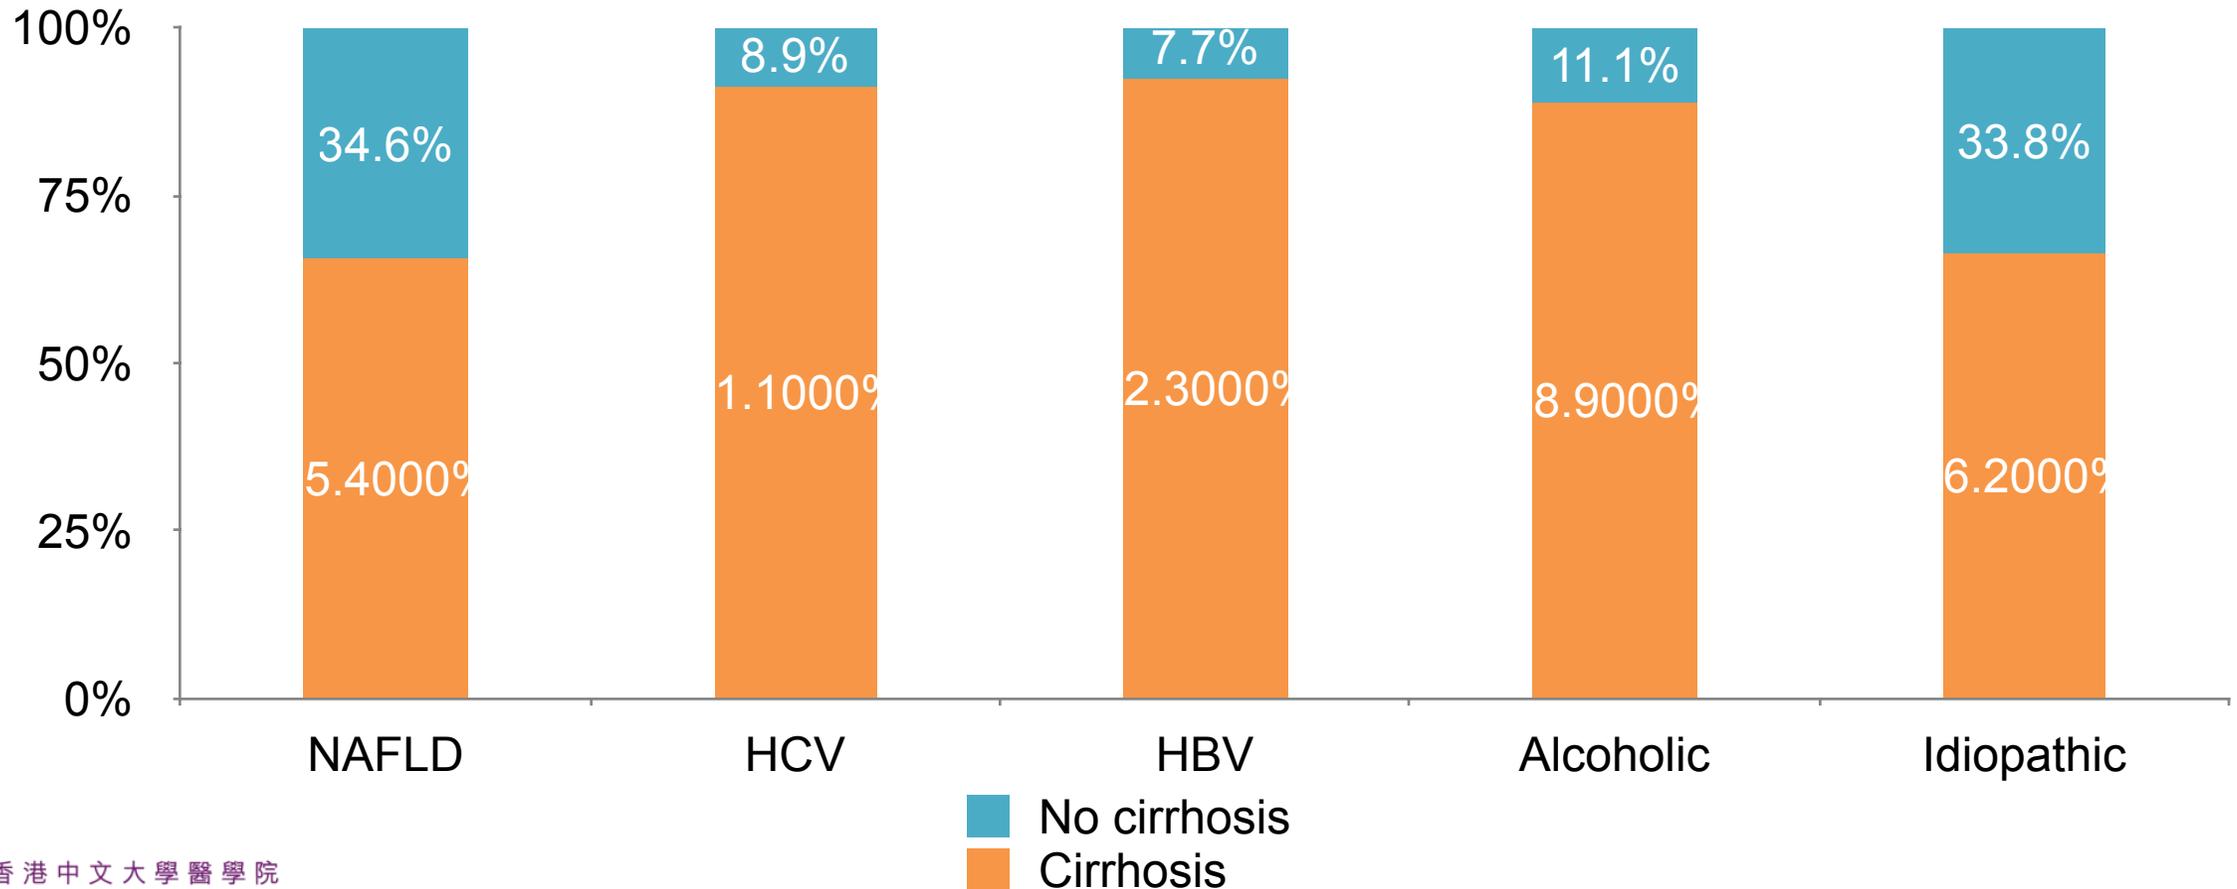

- FIB-4 low, LSM low
- FIB-4 low, LSM high
- FIB-4 high, LSM low
- FIB-4 high, LSM high

All fibrosis NITs perform better for predicting hepatic decompensation than HCC in the VCTE-Prognosis study

Tests	AUROC for decompensation at 3 years	AUROC for HCC at 3 years
Histologic fibrosis stage	0.86	0.85
Agile 3+	0.94	0.85
Agile 4	0.94	0.85
VCTE-LSM	0.92	0.77
FIB-4	0.89	0.75
NFS	0.89	0.76
APRI	0.85	0.70
FAST	0.81	0.74
AST/ALT ratio	0.71	0.63
BARD	0.73	0.61

Changes in FAST score during semaglutide treatment

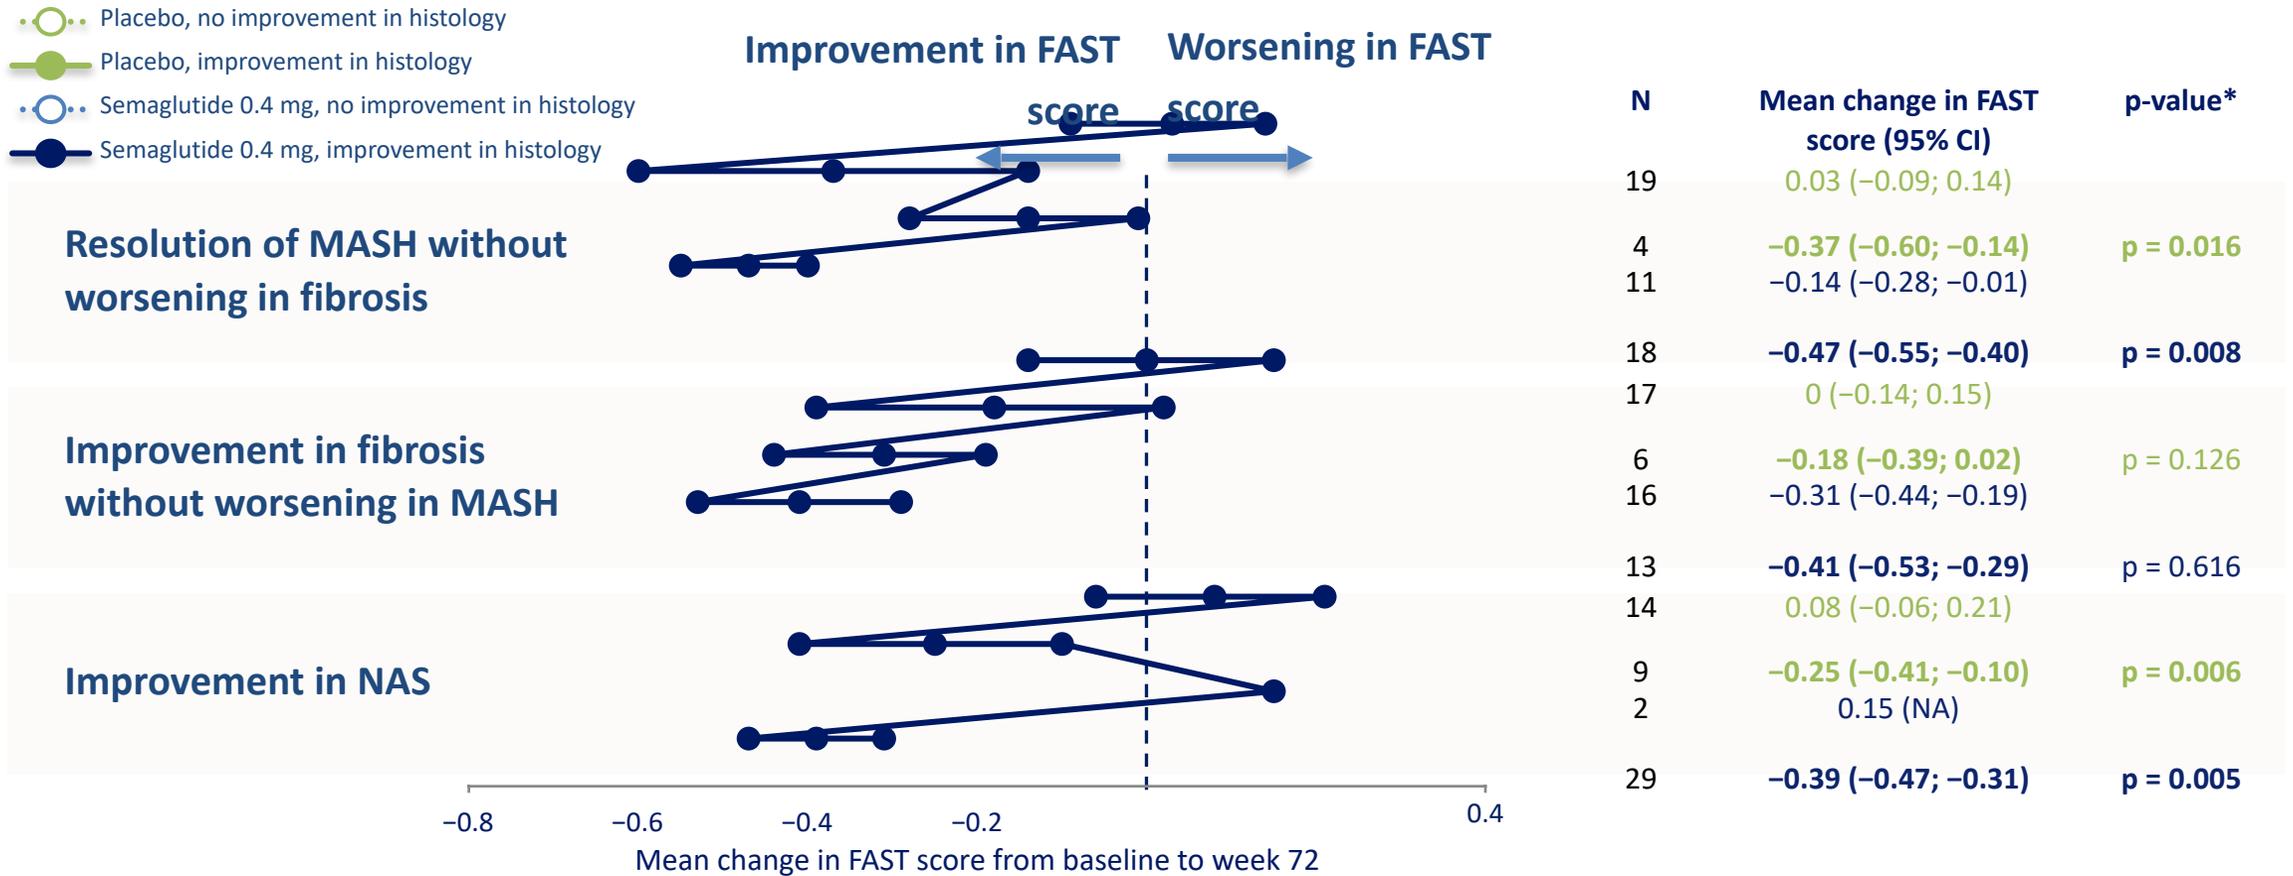

BASELINE TO WEEK 72 – SUBSET ANALYSIS (N=161)

● Semaglutide 0.1 mg OD ● Semaglutide 0.2 mg OD ● Semaglutide 0.4 mg OD

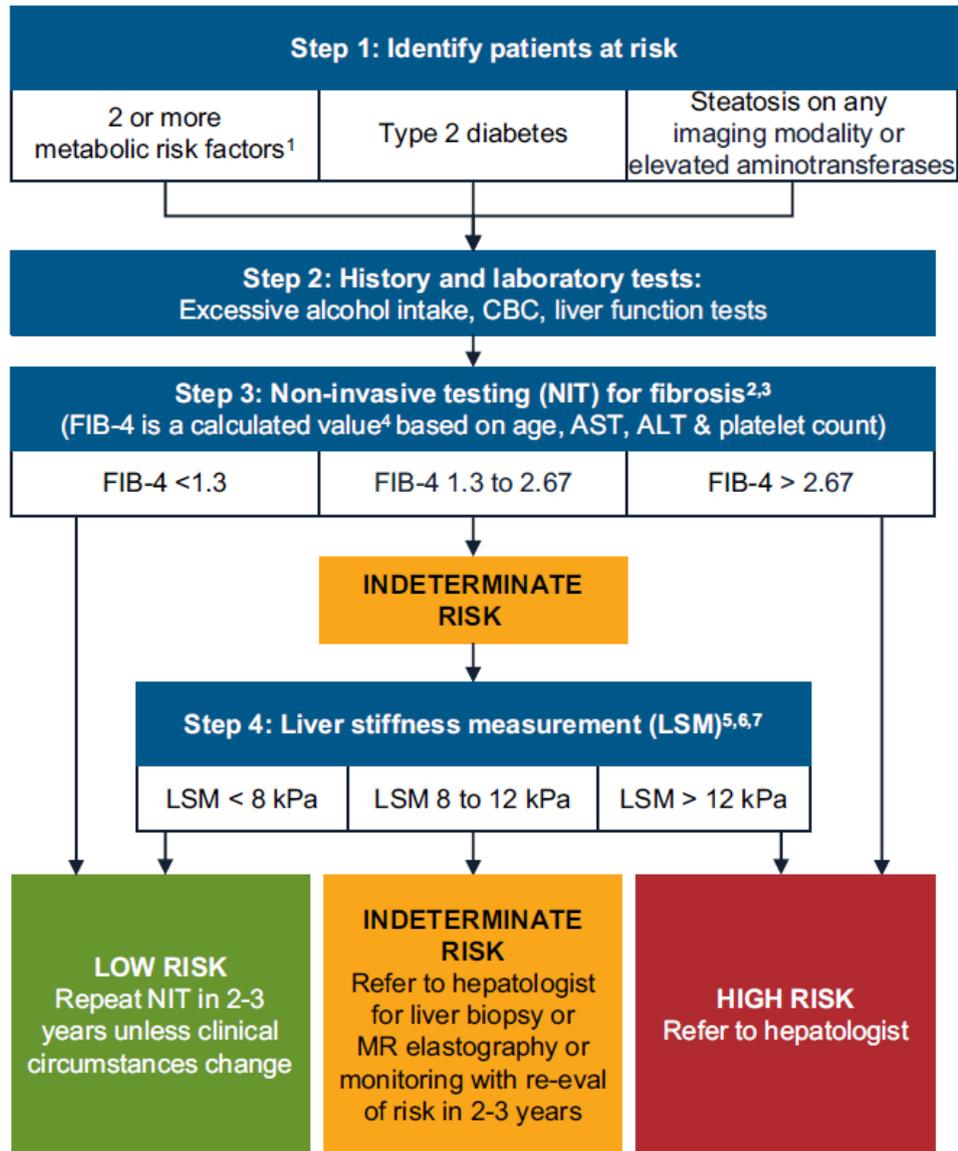

Changes in FAST score and histologic response

BASELINE TO WEEK 72

Data are from all randomized patients during the on-treatment period. Improvement assessed by histology. *p-value for comparisons between improvement in histology vs no improvement in histology. CI, confidence interval; FAST, FibroScan aspartate aminotransferase; NA, not applicable; NAS, non-alcoholic fatty liver disease activity score; MASH, metabolic dysfunction-associated steatohepatitis.

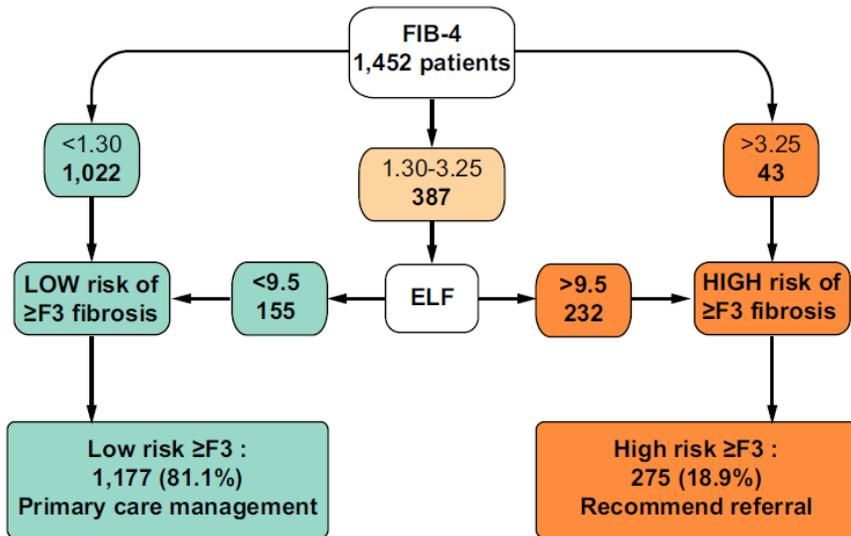

Primary care, endocrinologists, gastroenterologists, and obesity specialists should screen for NAFLD with advanced fibrosis

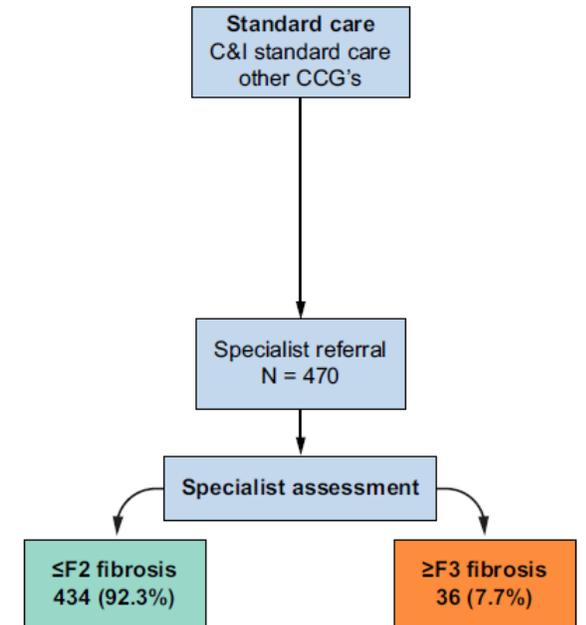

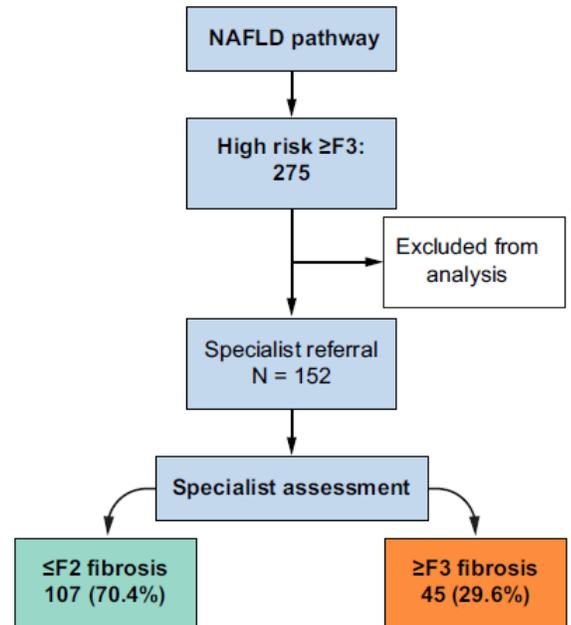

AGA Clinical Care Pathway for NAFLD

The Camden and Islington MASLD pathway for primary care settings

- Reduce unnecessary referrals by 80%
- Increase detection of advanced fibrosis by 5-fold, cirrhosis by 3-fold

Clinical care pathway to detect advanced liver disease in patients with type 2 diabetes through automated fibrosis score calculation and electronic reminder messages: a randomised controlled trial

Study Population

five general medical or diabetes clinics

1061 patients with type 2 diabetes were screened between 19 May 2020 and 14 October 2021

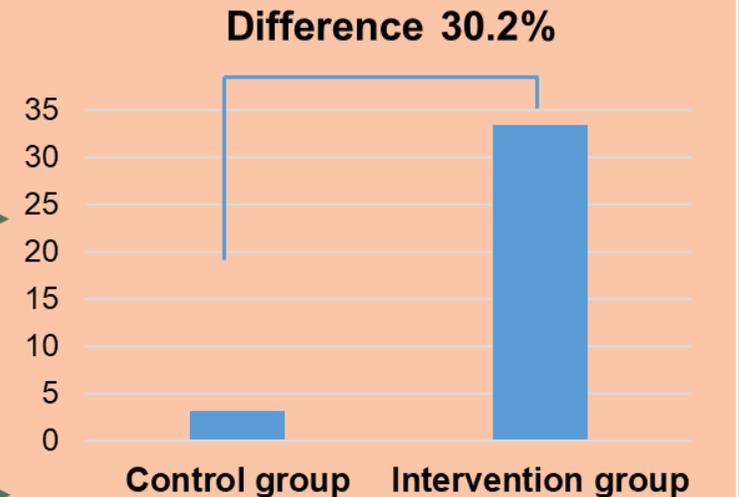

Intervention

Control (n=528):
fibrosis score calculation +
no electronic reminder messages

Intervention (n=533):
fibrosis score calculation +
electronic reminder messages if
abnormal fibrosis scores

Primary outcome:
Proportion of patients with high
fibrosis scores who received
hepatology care or further fibrosis
assessment

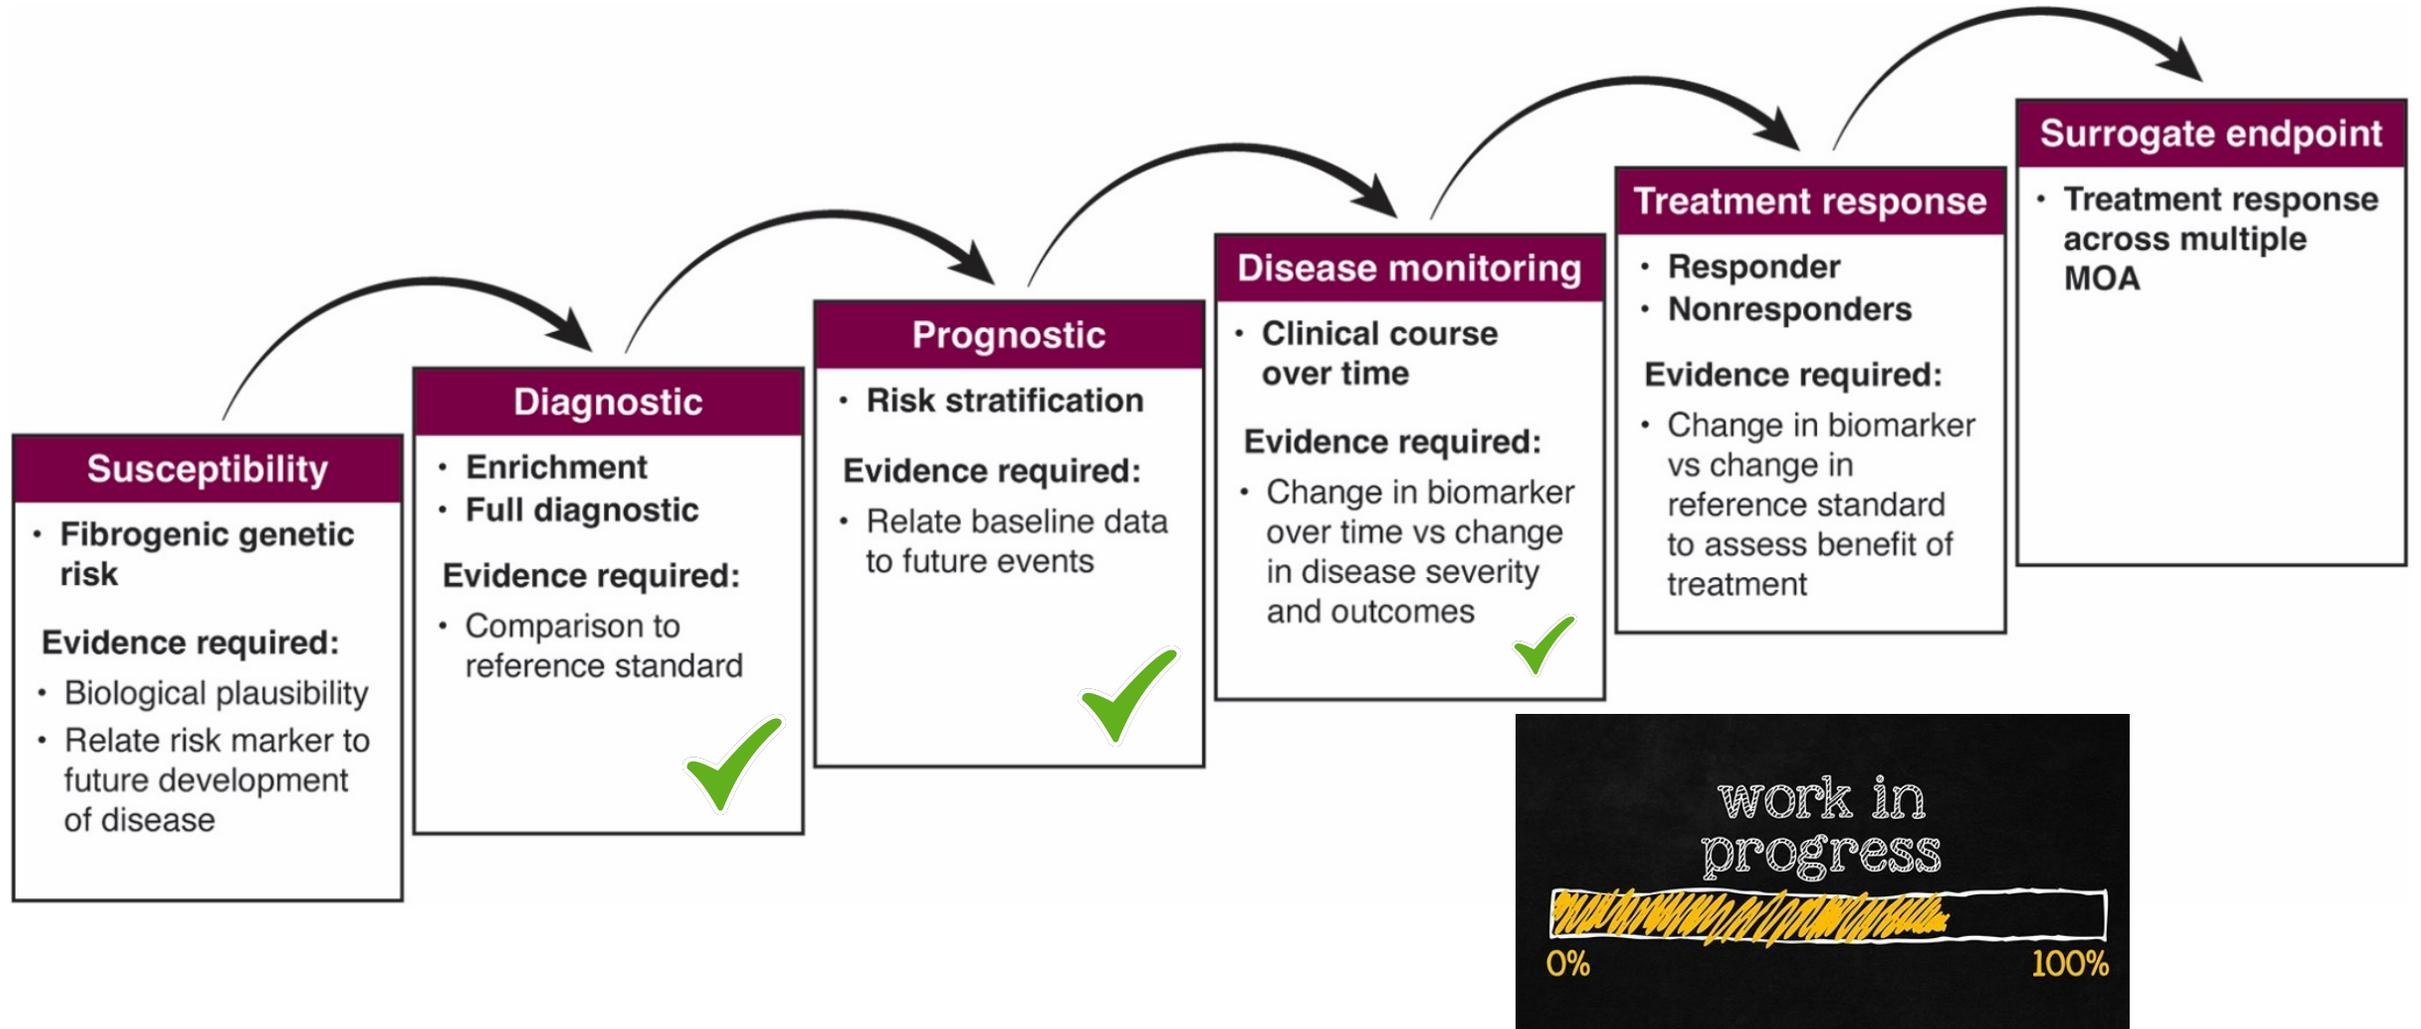

Outcome

Automated fibrosis score calculation and electronic reminders increase referral of patients with type 2 diabetes and abnormal fibrosis scores at non-hepatology settings
